COMPUTATIONAL MODELLING GROUP

21st May 2010

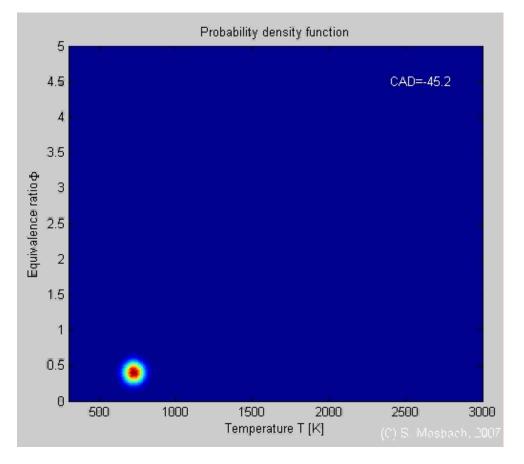

Stochastic Reactor Model (SRM)

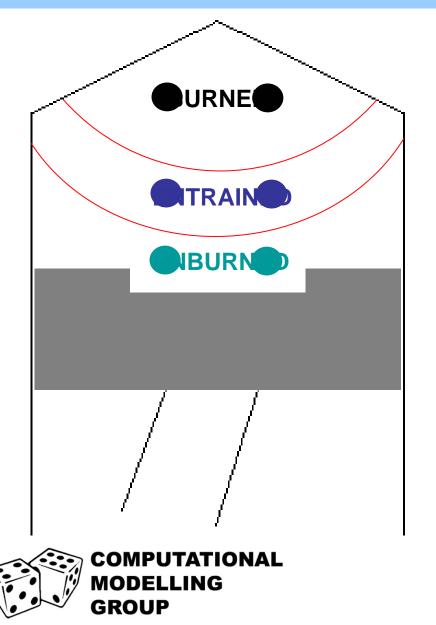

- Simulates closed-volume in-cylinder processes.
- Models turbulent mixing, convective heat transfer, direct injection, spark ignition, soot formation.
- Detailed chemical mechanism for PRF + NOx + soot precursors (208 species, 1002 reactions).

Test case: PFI and DI at 40 CAD BTDC

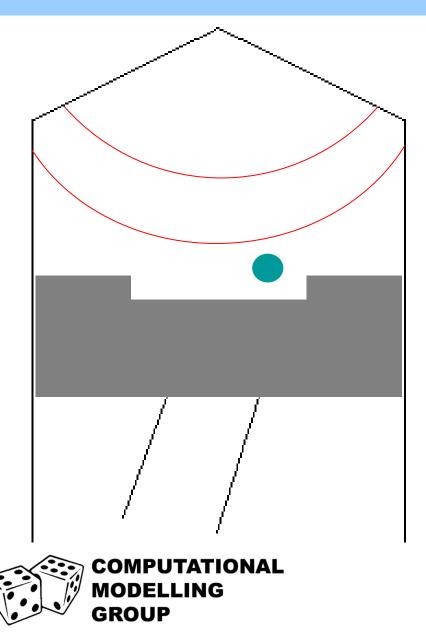

Markus Kraft mk306@cam.ac.uk

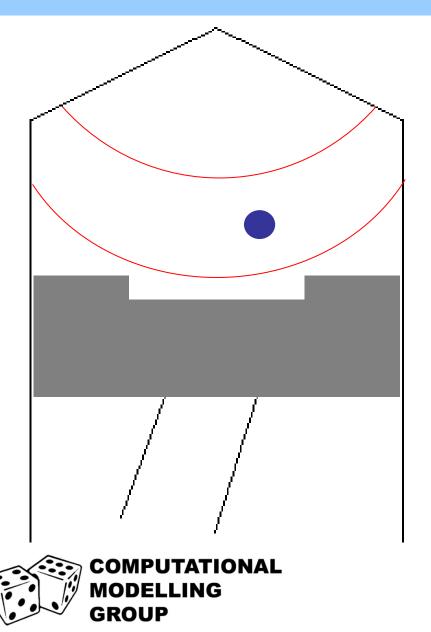

- The model contains three zones.
- Mixing occurs within each zone but not between zones.

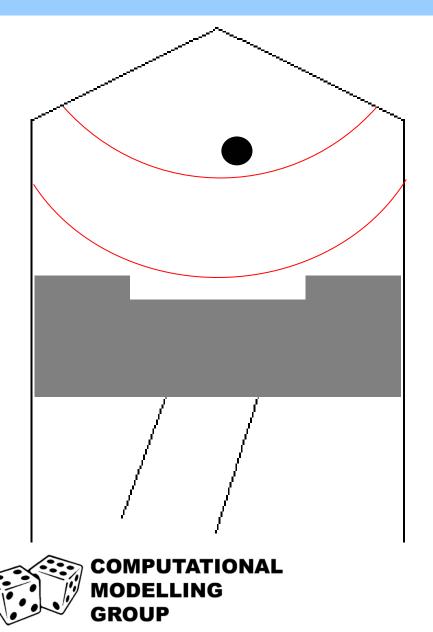

- The turbulent flame speed is used to calculate the new flame radius.
- When the calculated volume is greater than the particles' volume a new particle is added to the entrained zone.

 Particles move from entrained to burned zone once heat release rate goes above then drops below a certain value.

 The chemistry within each particle is calculated at each time step with the detailed mechanism.

SI engine CCV

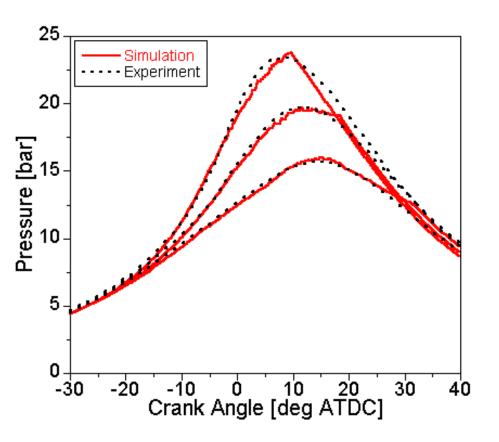

Fuel	gasoline
Bore	87.5 mm
Stroke	83.0 mm
Con. rod length	146.3 mm
Disp. volume	499 cm^3
CR	12.0
Speed	1500 RPM
Air/fuel equiv. ratio	1.0
EGR	28.8%

SI model calibration

• Characteristic flame speed obtained from:

$$u_T = 0.08 C \bar{u}_i \left(\frac{\rho_u}{\rho_i}\right)^{1/2}$$

 Constant, C, calibrated to match representative slow, medium and fast cycles.

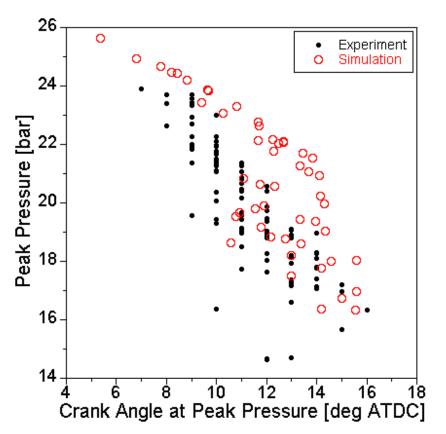

SI model calibration

- Relation between C and the peak pressure obtained.
- Used with peak pressure distribution to provide C during each cycle of a multi-cycle simulation.

Multi-cycle SI simulation

- Model coupled to GT-Power for multi-cycle simulation.
- 50 simulated and 96 experimental cycles.
- NO_x emissions:
 - 790 ppm simulation
 - 530 ppm experiment

DISI engine

Image from www.engineforall.com

- Late injection produces stratified mixture.
- Fuel rich regions close to spark gap.

DISI engine experiments

- Data from Maricq *et al.*, SAE 1999-01-1530.
- Fuel comprised of 60% paraffin and 40% aromatic compounds.
- Fuel modelled as 60% isooctane and 40% toluene.
- Exhaust measurements for various injection timings.

Problem

Current engine model development

- Experimental data in a variety of formats, sometimes largely unstructured, often incomplete
- Uncertainties/errors associated with experimental data typically unknown or unavailable
- Too many models and "tuneable"/unknown model parameters
- How "good" (or not) is a particular model?

=> Ad hoc, fragmented, short-term approach

Solution: Process Informatics

We need a robust **integrated methodology** to help us work systematically and efficiently:

- Effective use of cost-intensive experimental data through data standardisation
- Systematic and robust model development through systematic optimisation, taking into account uncertainties
- Suggesting "useful" future experiments

SAE 2010-01-0152

A data model: engineML

Consistent format

- point data (e.g. rpm, CO, u)
- time resolved data (p-CA)
- apparatus (production engine, research engine)
- errors
- data type (consistent units)
- raw or processed
- experimental or model

eXtensible Markup Language (XML)

- machine and human readable, tagged with metadata
- highly structured (tree), easily queried
- can be validated against schema

Easily accessible database

- read by model code
- data stored consistently
- old data never "lost"

COMPUTATIONAL MODELLING GROUP Markus Kraft mk306@cam.ac.uk

Model parameter optimisation

We must accept that model parameters exist and have to be tuned to experimental data!

What is the best way to fit these parameters?

- As many data points as possible
- Uncertainties in experimental data as well as model parameters must be accounted for
- Use experimental data to reduce model parameter uncertainties
- Use experimental and model uncertainties to identify possible outliers in the data, or model shortcomings

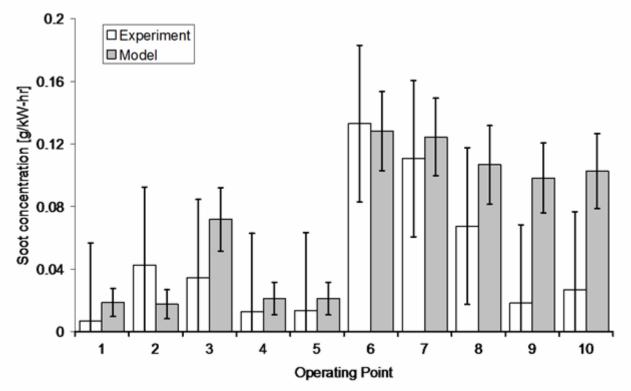

Application: Diesel soot

Empirical soot model (Plee):

 $soot[g] = A \cdot mps^{B} \cdot phi^{C} \cdot \exp\left(\frac{D}{T_{c}}\right)$

Optimised parameters A, B, C, D, against database of 503 operating points from 7 engines

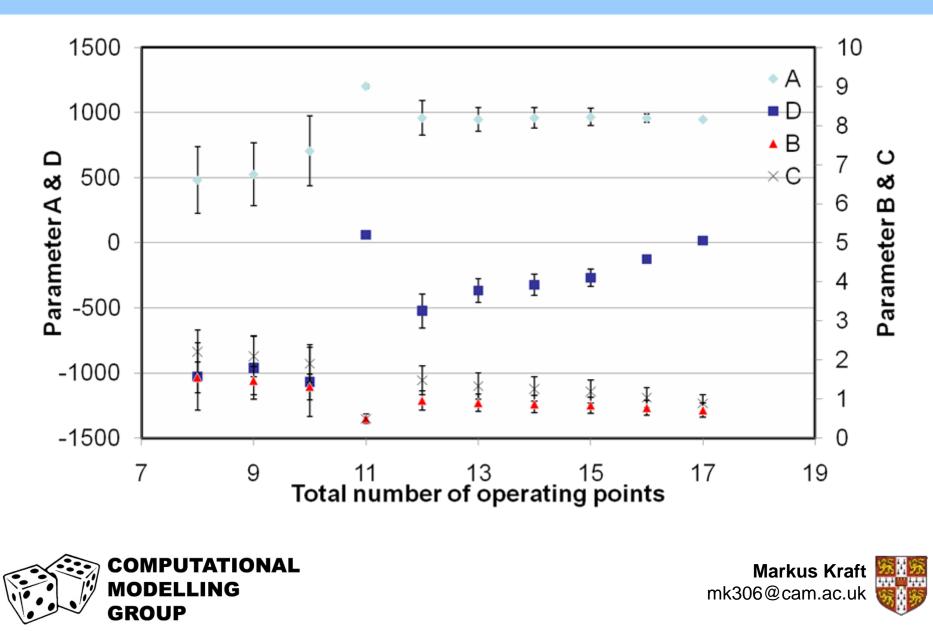

Example engine

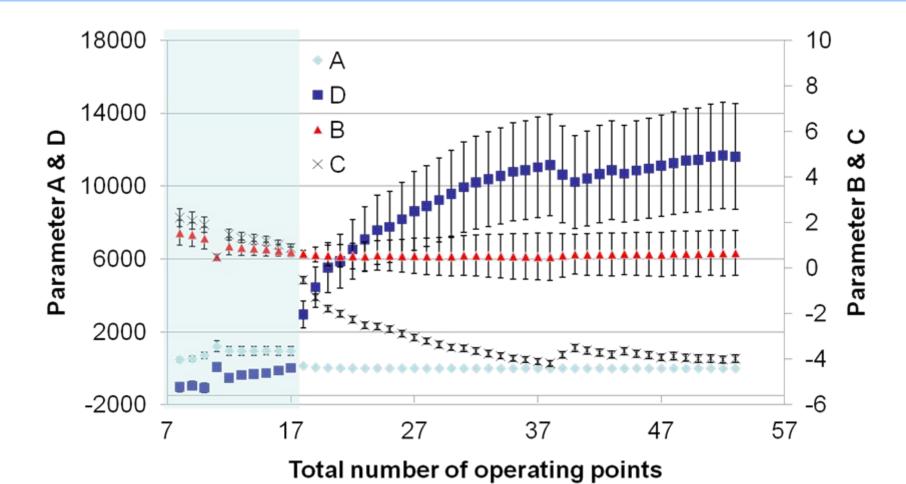

Parameter optimisation

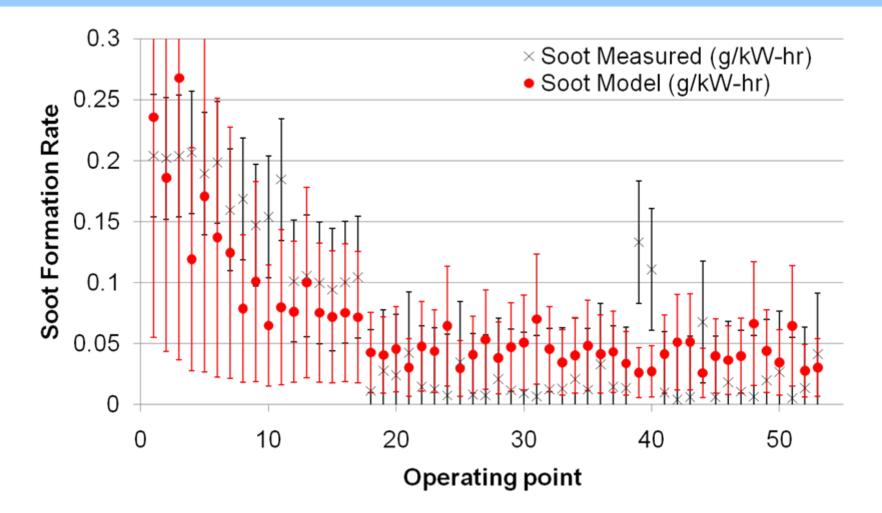

Add data from second engine

COMPUTATIONAL MODELLING GROUP

Add data from second engine

Summary

- Initial results of detailed soot modelling in a DISI engine have been presented, though, with room for improvement.
- A Process Informatics based methodology has been proposed for robust engine model development.
- A standardised, machine-readable format, engineML, has been presented.
- Optimisation results including model parameter and experimental uncertainties have been presented for an empirical diesel soot model.

Thank you!

Welcome!

Welcome to the website of the Computational Modelling Group! We develop and apply modern numerical methods to problems arising in Chemical Engineering. The overall aim is to shorten the development period from research bench to the industrial production stage by providing insight into the underlying physics and supporting the scale-up of processes to industrial level.

The group currently consists of 20 members from various backgrounds. We are keen to collaborate with people from both within industry and academia, so please get in touch if you think you have common interests.

The group's <u>research</u> divides naturally into two inter-related branches. The first of these is research into mathematical <u>methods</u>, which consists of the development of stochastic particle methods, computational fluid dynamics and quantum chemistry. The other branch consists of research into <u>applications</u>, using the methods we have developed in addition to well established techniques. The main application areas are reactive flow, combustion, engine modelling, extraction, nano particle synthesis and dynamics. This research is <u>sponsored</u> on various levels by the UK, EU, and industry.
